## 1

### 1.a

Figure 1 shows the function  $u(t) = 1/(1.1 - \cos t)$  and the polynomial interpolation  $p(t)$  using 11 equidistant points.

The interpolation is performed using the functions *cos\_transform* and *inv\_cos\_transform*, shown below.

```
function a = cos_transform( U )
    n = length(U)-1;
    U_extended = [U; flip(U(2:end-1))];           % Extend U by mirroring. U is even and periodic

    c = fft(U_extended)./length(U_extended);
    a = [c(1); c(2:n)+c(end:-1:n+2); c(n+1)];      % cosine coefficients a_0,...,a_n
end

function U = inv_cos_transform( a )
    n = length(a)-1;
    b = zeros(length(a)-2, 1);
    c = [a(1); a(2:end)/2; zeros(n-1,1)] + [zeros(n,1); a(end:-1:2)/2] + ...
        [0; b/2i; 0; -b(end:-1:1)/2i];

    U = ifft(c)*length(c);
    U = U(1:length(U)/2);                          % remove extended part of the function
end
```

### 1.b

Figure 2 shows how the error  $\|u - p_n\|_\infty$  decays as  $n$  increases. The Log of the error drops linearly which indicates exponential convergence.

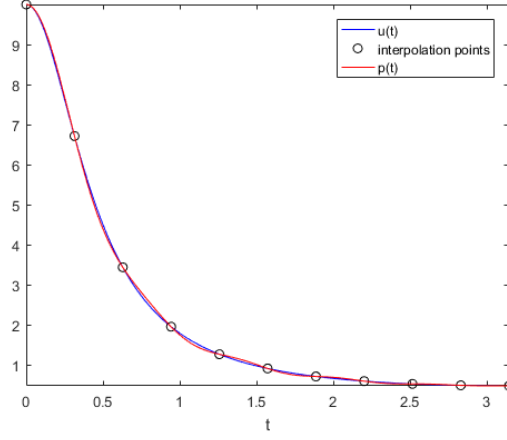

Figure 1:  $u(t)$  and the interpolating polynomial  $p(t) \in \mathcal{P}_{10}$ . Using 11 equidistant nodes.

Below you can see the output produced when estimating the error for  $n = 2, 4, \dots, 50$ . N is the order of the polynomial. E is the error estimate  $E_n$ . S is the slope between the points  $(n-2, \log E_{n-2}), (n, \log E_n)$ .

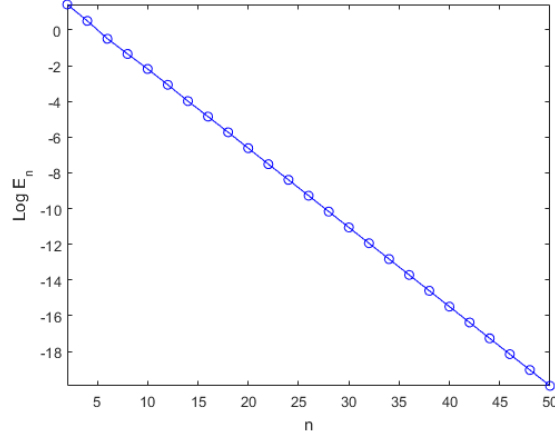

Figure 2: The error  $\|u - p_n\|_\infty$  drops exponentially as  $n$  increases.

### 1.c

The function  $f(z) = (1.1 - \frac{1}{2}(z + z^{-1}))^{-1}$  has two non-continuous jumps, where  $z = 0.641742$  and  $z = 1.55826$ . Those are the values of  $\rho$  and  $\rho^{-1}$  that define the region of convergence.

### 1.d

Figure 3 shows the function  $v(x) = |x|^{1/3}$  and the polynomial interpolation  $p(t)$  using 9 Chebyshev nodes.

## 2

### 2.a

The function *interperr\_eq* approximates the function  $u(x) = (1 + 30x^2)^{-1}$  with the interpolating polynomial  $p_n(x)$  using  $n + 1$  equidistant nodes. Using Lagrange formula with equidistant nodes suffers from Runge's phenomenon. It oscillates far from the true value at the edges of the range.

Figure 4 shows the error  $\|u - p_n\|_\infty$  goes down at first but then increases exponentially as  $n$  increases. The oscillation get worse and worse as  $n$  increases.

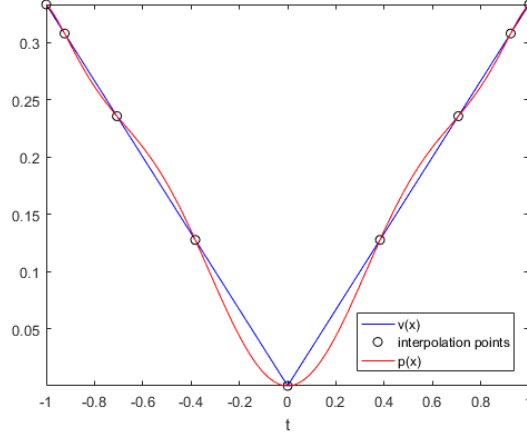

Figure 3:  $v(x)$  and the interpolating polynomial  $p(x) \in \mathcal{P}_8$ . Using 9 Chebyshev nodes.

To roughly estimate the decay rate  $\alpha$ , I divided the range of  $E$  with the range of  $n$  to get a slope. Figure 4 shows the line  $\log Ce^{\alpha n}$  using the estimate for  $\alpha$  and it does satisfy the condition  $E_n \leq Ce^{\alpha n}$ . In this case  $\alpha = 0.29310$  and  $C = 0.4$ .

```
function err = interperr.eq( n )
    np = 1000; % Number of points to plot with
    u = @(x) (1./(1+30*x.^2)); % function u(x)

    x = -1 + (0:n)' * 2/n;
    xp = -1 + (0:np-1)' * 2/np;

    U = u(x); % Evaluate u(x)
    Px = modlagr(x, U, xp);
    Ux = u(xp);

    err = max(abs(Px - Ux));
end
```

## 2.b

The function *interperr\_ch* approximates the function  $u(x) = (1 + 30x^2)^{-1}$  with the interpolating polynomial  $p_n(x)$  using  $n + 1$  Chebyshev nodes. By using Chebyshev nodes the oscillation issue is fixed. Nodes are placed closer together at the edges of the range.

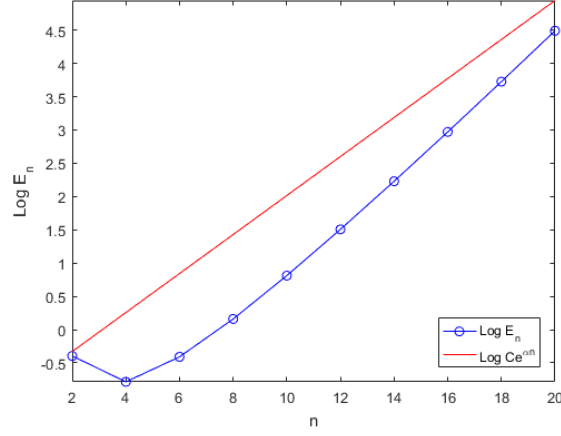

Figure 4:  $\text{Log} E_n$  and a rough estimate of the decay rate  $\alpha$

Figure 5 shows the error  $\|u - p_n\|_\infty$  decreases exponentially as  $n$  increases. It also shows a rough estimate for  $\alpha$  as the line  $\log C e^{\alpha n}$ , it does satisfy the condition  $E_n \leq C e^{\alpha n}$ . In this case  $\alpha = -0.18374$  and  $C = 1.04$ .

```
function err = interperr.ch( n )
    np = 1000; % Number of points to plot with
    u = @(x) (1./(1+30*x.^2)); % function u(x)

    t = (0:n)' *pi/n;
    tp = (0:np-1)' *pi/np;
    x = cos(t);
    xp = cos(tp);

    U = u(x); % Evaluate u(x)
    Px = modlagr(x, U, xp);
    Ux = u(xp);

    err = max(abs(Px - Ux));

%% plot u(t)
plot(xp, Ux, '-', 'color', 'blue'); hold on; % Plot function u(t)
plot(x, u(x), 'o', 'color', 'black'); % Plot interpolation points
plot(xp, Px, '-', 'color', 'red'); % Plot function p(t)
hold off;
end
```

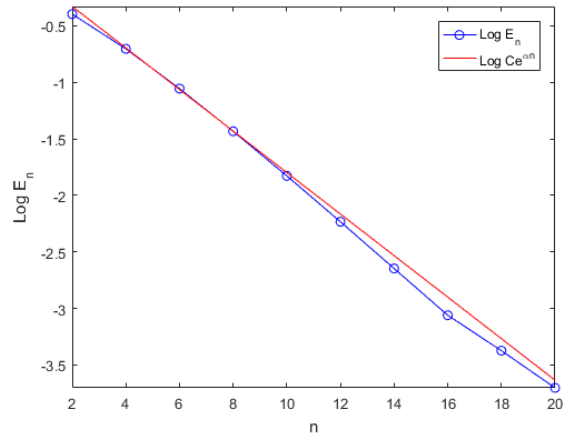

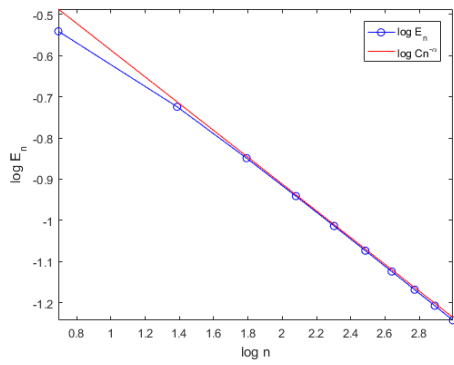

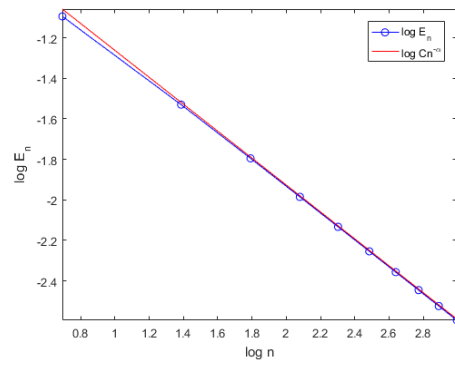

Figure 5:  $\text{Log} E_n$  and a rough estimate of the decay rate  $\alpha$

(a)  $u_1$

(b)  $u_2$

## 2.c

This shows the output when estimating the interpolation error  $\|u - p_n\|_\infty$ .  $u(x) = |x|^{1/3}$ . N is the degree of the polynomial. E is the log of the error. S is the slope between the points  $(\log(n-2), \log E_{n-2}), (\log n, \log E_n)$ .

N: 4	E: 0.48476	S: -0.26463
